Psychrometers are precision devices containing a dry and a moistened temperature sensor. As a result of the evaporation the humidity sensor cools down, with a wind velocity of a minimum of 2m/s being required for the cool down process. The humidity values are calculated from the temperature difference (psychrometric difference).

Absolute humidity is the measurement of water in its gas state in comparison to a meter of air. Grams are used to measure the water vapor, and the air is measured in cubic meters. That sounds simple enough, but barometric pressure and other variables drastically impact the air, and that makes it difficult to get useful information from absolute humidity readings.

While a hygrometer is normally used to check moisture levels, you can use alternative methods as well. To ensure comfort, the humidity in your dwelling should register between 40% and 50%. To learn how you can ensure this type of comfort, you need to learn more about humidity so you can accurately measure it.

There are three main measurements of humidity: relative, absolute and specific. Absolute humidity (units are grams of water vapor per cubic meter volume of air) is a measure of the actual amount of water vapor in the air, regardless of the air's temperature. The higher the amount of water vapor, the higher the absolute humidity.

The humidity of a gas may be measured by a variety of techniques. Some are based on the determination of the partial pressure of vapor in the gas (e.g., dew point determination); the relationship between humidity and partial pressure is given in the entry entitled Humidity.
